

Task 1 - QA and Debug Report

Name: Taha Ansari

Date: 30 September 2026

App tested: RealWorld (Conduit) Angular frontend, run locally at localhost:4200, using the hosted API api.realworld.show

Summary

I tested the app with Playwright scripts and some manual checks, and found 11 issues. Each one reproduced in all 5 runs. The most serious is Bug 2: a user can save an invalid email in Settings and after that cannot log in with their real email. Most of the others are about missing error handling, no delete confirmation and accessibility. I did not change any app code. Things that worked fine: script injection (XSS) was blocked, other users' articles can't be edited, logout then Back does not show private pages, and the mobile layout (375px) is okay.

Bug table

#	Title / Summary	Steps to Reproduce	Expected vs Actual	Severity	Suspected Cause
1	Duplicate article when Publish is clicked twice very fast	1. Log in 2. Go to New Article and fill the form 3. Click Publish twice within a few milliseconds (done with a script) 4. Check My Articles	Expected: one article. Actual: two same articles. Normal double clicks by hand did not do this.	Low	Publish button is not disabled after the first click.
2	Invalid email (abc@) gets saved in Settings and then I can't log in	1. Log in 2. Open Settings 3. Change email to abc@ and click Update Settings 4. Log out 5. Log in with the old real email	Expected: error message and email stays the same. Actual: server returns 200 and saves it. Login with the real email then gives 401.	High	No email format check when updating settings.
3	Delete Article has no confirmation	1. Log in and open your own article 2. Click Delete Article	Expected: an "Are you sure?" popup. Actual: article is deleted right away.	Medium	Button calls the delete API directly.
4	Blank page for a missing article or profile	1. Open an article or profile URL that does not exist	Expected: a "not found" message. Actual: blank page, even though the server sends a 404 with a message.	Medium	Frontend ignores the error response.
5	Comment delete icon can't be reached with keyboard	1. Open an article with your own comment 2. Press Tab again and again	Expected: delete icon gets focus and works with Enter. Actual: focus never reaches it, so only mouse users can delete.	Medium	Probably not a real button element.

#	Title / Summary	Steps to Reproduce	Expected vs Actual	Severity	Suspected Cause
6	Double click on Favorite makes the button go out of sync	1. Open an article 2. Double click Favorite 3. Reload and compare	Expected: button matches the real state. Actual: button shows a different state than the server.	Low	Two requests run together, no guard for that.
7	Confusing error for a long title	1. Start a new article 2. Enter a title longer than 100 characters 3. Click Publish	Expected: something like "Title must be under 100 characters". Actual: "body title is a string of less than 100 chars".	Low	Raw backend message shown as it is.
8	Unknown URL shows an empty page	1. Open a wrong URL like /some-random-page 2. Check the console	Expected: a 404 page or redirect to home. Actual: empty page and a router error in the console.	Low	No catch-all route.
9	Accessibility: no alt text, no form labels, no page language	1. Open the app 2. Inspect images, form fields and the html tag in DevTools	Expected: alt text, labels and a lang attribute. Actual: all three are missing.	Medium	Attributes were never added in the templates.
10	Home feed says "Loading articles..." forever when API fails	1. Force the articles request to return 500 (Playwright) 2. Open the home page	Expected: an error message and a retry option. Actual: loading text stays forever.	Low	No error handling on the request.
11	Failed delete shows nothing and the button gets stuck	1. Force the delete request to return 500 (Playwright) 2. Click Delete Article	Expected: error message and button works again. Actual: nothing shown, button stays stuck.	Low	No error handling on the delete request.

Note: Bugs 10 and 11 need a server failure, so I forced a 500 response in Playwright. The rest happen with the real API. The suspected causes come from what I saw and the frontend code. There was no local backend, so server side causes are my guess from the responses.

Root cause analysis - Bug 2 (invalid email saved in Settings)

When I changed my email to abc@ in Settings and clicked Update Settings, the app accepted it and the server replied with 200 OK. So the wrong email was saved on the account. After that, logging in with my real email returned 401, because the server no longer had that email. This means the user is locked out of their own account, so I marked it High. The reason is that nothing checks the email format, neither the Settings form nor the update API. I saw the 200 response on update and the 401 on login in all 5 runs. To fix it, I would add an email validator to the Settings form so the error shows before sending. I would also validate on the server and return a 422 with a clear message, because frontend checks can be skipped. Sending a confirmation link to the new email before changing it would be even safer. Lastly I would add a test that submits abc@ and checks that an error appears and the email stays the same.

Evidence

Screenshots, notes and Playwright tests are in the task1 folder of my GitHub repo (task1/screenshots, task1/notes.md, task1/tests).
